Distinct stem cells contribute to mammary gland development and maintenance

Alexandra Van Keymeulen1*, Ana Sofia Rocha1*, Marielle Ousset1, Benjamin Beck1, Gaëlle Bouvencourt1, Jason Rock2, Neha Sharma1, Sophie Dekoninck1 & Cédric Blanpain1,3

The mammary epithelium is composed of several cell lineages including luminal, alveolar and myoepithelial cells. Transplantation studies have suggested that the mammary epithelium is maintained by the presence of multipotent mammary stem cells. To define the cellular hierarchy of the mammary gland during physiological conditions, we performed genetic lineage-tracing experiments and clonal analysis of the mouse mammary gland during development, adulthood and pregnancy. We found that in postnatal unperturbed mammary gland, both luminal and myoepithelial lineages contain long-lived unipotent stem cells that display extensive renewing capacities, as demonstrated by their ability to clonally expand during morphogenesis and adult life as well as undergo massive expansion during several cycles of pregnancy. The demonstration that the mammary gland contains different types of long-lived stem cells has profound implications for our understanding of mammary gland physiology and will be instrumental in unravelling the cells at the origin of breast cancers.

The mammary gland is composed of epithelial cells and mesenchymal cells, including adipocytes, fibroblasts, blood vessels and immune cells1. Initially visible as placode-like structures, mammary glands are specified along the ventral epidermis during embryonic development and progressively invade the underlying mesenchyme, called the mammary fat pad. At puberty, the mammary gland expands considerably to form a highly branched tubular structure that progressively fills the fat pad. During pregnancy, the mammary gland expands further and the terminal end tubular structures differentiate into milk-producing cells. Two main cellular subtypes comprise the mammary gland epithelium: the basal myoepithelial cells and luminal cells, which can differentiate either into ductal cells or milk-producing cells (Supplementary Fig. 1). Whereas alveoli and luminal cells secrete the water and nutrients, the myoepithelial cells, through their contraction, guide the circulation of the milk throughout the ductal tree1–3.

Different assays have been developed to define the differentiation potential of mammary epithelial cells (MECs)2,4,5. In vitro assays indicated that both luminal cells and myoepithelial cells can be maintained with their lineage-restricted differentiation potential in a specific medium but only luminal cells can be forced to differentiate into myoepithelial cells upon medium switch6. Culture of fluorescence-activated cell sorting (FACS)-isolated human MECs gives rise to either luminal or myoepithelial colonies as well as some bipotent colonies6–8. Culturing MECs as non-adherent cells, called mammospheres, allowed renewal and differentiation of cells with unipotent and bipotent differentiation potential8. Transplantation of primary MECs at limiting dilutions suggested the presence of multipotent mammary stem cells and more committed progenitors9–11, and a single MEC is able to reconstitute an entire functional mammary gland in serial transplantation12. Transplantation of a single FACS-isolated MEC can constitute, although at low frequency, a normal mammary gland12,13, indicating that rare multipotent mammary stem cells reside at the top of the cellular hierarchy within the mammary gland. Although transplantation studies are important to define the differentiation potential of stem cells, these assays mimic a regenerative state that in certain circumstances forces stem cells to differentiate into lineages for which they usually do not contribute to under physiological conditions. For example, hair follicle bulge stem cells give rise to all epidermal lineages upon transplantation and wound healing, but only to hair follicle regeneration under physiological conditions4. The definitive demonstration that, under physiological conditions, multipotent stem cells are responsible for the development and adult maintenance of the mammary epithelium awaits genetic lineage-tracing experiments13. Here we developed novel lineage-tracing approaches in mice to decipher the cellular hierarchy of the mammary epithelium during physiological conditions.

Multipotent embryonic K14 progenitors

We first assessed the contribution of K14-derived cells to mammary gland development and adult life using K14-Cre/Rosa-YFP mice. The mammary placode arises from the embryonic epidermis at embryonic day 14 (E14). At E17, all MECs expressed K14 and were YFP+/ in K14-Cre/Rosa-YFP mice and remained YFP+ thereafter (Supplementary Figs 2 and 3). During the early stage of mammary gland development, K14 expression encompassed both myoepithelial cells and a fraction of luminal cells (Fig. 1a–c). At birth, the mammary gland consisted of a tubular epithelial structure composed of basal myoepithelial cells expressing K5, K14 and SMA and luminal cells expressing K8 and K19. At the beginning of puberty and thereafter, K14 expression was restricted to the myoepithelial lineage (Supplementary Figs 1 and 2). FACS analysis of mammary gland from K14-Cre/Rosa-YFP mice revealed that all YFP-labelled cells expressed CD24, as previously suggested15, and could be divided into two populations: CD29+/CD24+ enriched for myoepithelial cells and CD29−/CD24− enriched for luminal cells2,13 (Supplementary Figs 4 and 5). Because K14-Cre is expressed in myoepithelial cells after birth, we investigated whether all MECs derive from embryonic K14+ progenitors by administrating

*These authors contributed equally to this work.
a single dose of doxycycline to pregnant K14-rtTA/TetO-Cre/Rosa-YFP mice at E17 to label MECs during development (Supplementary Fig. 6). Analysis of the mammary gland at puberty showed that embryonic labelling marked the majority of MECs, including both myoepithelial cells and luminal cells, demonstrating that embryonic K14 progenitors give rise to all MEC lineages (Fig. 1d–g).

K14 myoepithelial stem cells

The transcriptional profiling of CD29<sup>Hi</sup>CD24<sup>+</sup> cells revealed that the putative multipotent mammary stem cells<sup>2,13</sup> are enriched for K5 and K14 (refs 12, 13, 16, 17). To determine whether postnatal K14<sup>+</sup> cells contain multipotent mammary stem cells, we performed inducible genetic lineage-tracing experiments of K14-expressing cells during puberty and in adult virgin mice. Doxycycline administration over 5 days in K14-rtTA/TetO-Cre/Rosa-YFP mice induced YFP expression in about 40% of myoepithelial cells but did not label luminal cells (Fig. 2a, b, e and Supplementary Figs 7 and 8). Surprisingly, 10 weeks after doxycycline administration, YFP was still exclusively expressed by myoepithelial cells (Fig. 2c–e and Supplementary Figs 7 and 8). To rule out that the remaining CD29<sup>Hi</sup>CD24<sup>+</sup> myoepithelial cell population that was not labelled in the previous experiments contains multipotent mammary stem cells, we administered doxycycline continuously to K14-rtTA/TetO-Cre/Rosa-YFP mice during the whole process of pubertal development and found that almost all myoepithelial cells (>97%) but no luminal cells were labelled (Fig. 2f, g and Supplementary Fig. 7m). These data demonstrate that the K14-expressing cells do not contribute to the luminal lineage during mammary gland expansion that occurred during pubertal development.

Administration of a low dose of doxycycline to K14-rtTA/TetO-Cre/Rosa-YFP 4-week-old mice resulted in the labelling of isolated myoepithelial cells 1 week after doxycycline administration. These cells were maintained for several weeks and about 10% of them expanded over time (Fig. 2h, i and Supplementary Fig. 9). YFP<sup>+</sup> myoepithelial cells expanded further during pregnancy and lactation. Some of them escaped mammary gland involution and reinitiated another cycle of expansion during the following pregnancy and were still present after the second mammary gland involution (Fig. 2j–l and Supplementary Fig. 10). The proportion of YFP-labelled cells was stable over time (Fig. 2l), showing that these unipotent stem cells undergo long-term self-renewal and are not replaced by multipotent stem cells over time.

Doxycycline administration to K14-rtTA/TetO-Cre/Rosa-YFP mice at postnatal day 1 (P1) marked mostly myoepithelial cells and gland at E17. d, e, Immunostaining of K5 (d) or K8 (e) and YFP in K14-rtTA/TetO-Cre/Rosa-YFP MECs 5 weeks after doxycycline administration. FACS analysis of CD24 and CD29 expression in Lin<sup>−</sup> YFP<sup>+</sup> cells 5 weeks after doxycycline administration. g, YFP expression in Lin<sup>−</sup>CD29<sup>Hi</sup>CD24<sup>+</sup> and Lin<sup>−</sup>CD29<sup>−</sup>CD24<sup>+</sup> populations 5 weeks after doxycycline administration, showing that embryonic K14 tracing marked the vast majority of MECs (n = 3 mice). Scale bars, 10 μm; error bars indicate s.e.m.

Some of them escaped mammary gland involution and reinitiated another cycle of expansion during the following pregnancy and were still present after the second mammary gland involution (Fig. 2j–l and Supplementary Fig. 10). The proportion of YFP-labelled cells was stable over time (Fig. 2l), showing that these unipotent stem cells undergo long-term self-renewal and are not replaced by multipotent stem cells over time.

Doxycycline administration to K14-rtTA/TetO-Cre/Rosa-YFP mice at postnatal day 1 (P1) marked mostly myoepithelial cells and
long-lived cells that display the ability to clonally expand during pregnancy and give rise to luminal and alveolar cells, and are therefore called parity-induced cells.\textsuperscript{19} Ex vivo culture of WAP-Cre mammary explants, in the presence of several growth factors, suggested that cells with similar renewal and differentiation potential as parity-induced mammary progenitors may already exist in nulliparous mice.\textsuperscript{19} To determine whether, under physiological conditions without ex vivo manipulations, luminal cells contain stem cells before pregnancy and whether these cells represent unipotent or multipotent stem cells, as has been previously suggested for human MECs,\textsuperscript{6} we generated transgenic mice expressing CreER in the luminal lineage using the K8 promoter (Supplementary Fig. 17a). Administration of tamoxifen to K8-CreER/Rosa-YFP mice at puberty (Supplementary Fig. 17). Similarly, tamoxifen administration to 4-week-old and adult virgin mice induced YFP expression only in luminal cells (Fig. 3a, b and Supplementary Figs 18 and 19), and after 10 weeks, YFP+ cells had expanded but were still luminal cells (Fig. 3c, d and Supplementary Figs 18 and 19), indicating that K8+ cells contain luminal stem cells.

Clonal analysis of K8+ cells by administration of a low dose of tamoxifen revealed that not all YFP+ cells persist long-term and at 4 weeks after tamoxifen administration 40% of YFP luminal clones were lost, indicating that K8-CreER also targets more committed luminal cells (Fig. 3e–h and Supplementary Figs 20–22). Temporal analysis of clone size revealed that about 10% of the YFP clones contained more than 5 YFP+ cells, some of which could be even much larger (Fig. 3g and Supplementary Fig. 21), consistent with the targeting of luminal stem cells that clonally expand and participate in luminal cell expansion during puberty and maintenance during adult life.

To establish further the renewal capacities of K8+ luminal stem cells and their contribution to milk-producing cells, we induced clonal YFP expression in luminal cells during puberty and followed their fate during pregnancy and lactation (Fig. 3i–l and Supplementary Fig. 23). During pregnancy, only clones of YFP+ luminal cells were found. During lactation, very large YFP clones were observed with some lobules that were almost entirely YFP+ whereas others were either negative or mosaic for YFP expression (Fig. 3j and Supplementary Fig. 23). K8-CreER-targeted cells differentiated into both luminal and milk-producing cells, as revealed by the co-expression of YFP with K8 and NaPiIIb in the fat-milk-producing cells; no myoepithelial cells were YFP+ (Fig. 3j and Supplementary Fig. 23d). After involution, some YFP+ cells persisted and were able to reinitiate another round of expansion during the following pregnancy and lactation and to escape cell death during the second involution (Fig. 3k and Supplementary Fig. 23). Even after three consecutive cycles of pregnancy and lactation, K8-derived cells were found in luminal cells and milk-producing cells (Supplementary Fig. 23–m). The percentage of YFP+ cells was stable over time (Fig. 3l), indicating that these cells are self-renewing long-term and are not progressively replaced by multipotent stem cells.

K8+ committed luminal cells

Different studies suggested that luminal cells are composed of morphologically distinct cell types that are thought to display different proliferation and differentiation capacities.\textsuperscript{21–23} We used another luminal inducible CreER (K18-CreER)\textsuperscript{24} to determine whether all luminal cells presented similar renewal and differentiation potential as compared to K8-CreER-targeted cells (Supplementary Figs 24–28). Administration of tamoxifen to 4- and 8-week-old K18-CreER/Rosa-YFP mice resulted in a patchy expression of YFP in the mammary gland. Only luminal cells were initially labelled and 10 weeks after tamoxifen administration, YFP-marked luminal cells were still present whereas no myoepithelial cells were YFP+ (Supplementary Figs 24 and 25). Clonal analysis during puberty and in adult virgin mice revealed no sign of important clonal expansion, even during pregnancy and lactation (Supplementary Figs 26–28). Together, these data suggest that the luminal cells targeted by K18-CreER display a low cellular turnover, and should be considered as more committed luminal cells, possibly representing the cells that are lost and/or failed to expand in K8 lineage-tracing experiments.

Transplantation and stem cell differentiation

To clarify the discrepancy between the results obtained in transplantation assays\textsuperscript{2,13} and our lineage-tracing experiments, we performed mammary reconstitution assays with cells labelled by our different myoepithelial- and luminal-specific Cre. Transplantation of 10\textsuperscript{6} dissociated mammary gland cells—which represent about 5×10\textsuperscript{6} living MECs from 4-week-old K14-Cre/Rosa-YFP mice—into the fat pad of NOD/SCID mice allowed the reconstitution of a morphologically normal mammary gland with YFP+ myoepithelial cells and luminal cells (Supplementary Fig. 29a–d).

To determine whether the transplantation procedure itself can promote the differentiation potential of YFP-labelled stem cells into the other lineage, we induced YFP expression in myoepithelial cells by administrating doxycycline to 4-week-old K14-rTA/TetO-Cre/Rosa-YFP mice. One week later the mammary gland was dissociated into single cells and a mixture of YFP+ myoepithelial cells together with unlabelled luminal cells was transplanted into the mammary fat pad of NOD/SCID mice (Supplementary Fig. 29a). Seven weeks after transplantation, the grafted cells regenerated a new mammary gland expressing YFP in the ducts and growing alveoli (Fig. 4a). Microscopic examination revealed that the vast majority of YFP+ cells were myoepithelial cells (Fig. 4b, c and Supplementary Fig. 29e–h) and only very rare clones expressing YFP in both myoepithelial cells and luminal cells were identified (Supplementary Fig. 29i, j and...

Scale bars, 10 μm unless stated; error bars indicate s.e.m.

Supplementary Table 1). Similar results were obtained after the transplantation of MECs labelled by K5-CreER (Supplementary Fig. 29k–m). Transplantation of YFP-marked luminal cells together with unlabelled myoepithelial cells after tamoxifen administration to K8-CreER/Rosa-YFP K8-CreER/Rosa-YFP mice resulted in the regeneration of a new mammary gland when the two types of unipotent stem cells are present together at non-limiting dilutions. To determine whether the presence of only one type of mammary stem cell during the transplantation procedure can expand their differentiation potential, FACS-isolated YFP+ myoepithelial or luminal cells were transplanted into the mammary fat pad of NOD/SCID mice (Supplementary Fig. 31a). As previously shown11,13, transplantation of FACS-isolated CD29loCD24+ luminal cells alone failed to reconstitute a new mammary gland upon transplantation whereas CD29hiCD24+ myoepithelial cells alone were able to regenerate a new mammary gland independently of the presence of luminal cells (Fig. 5a–c and Supplementary Table 1). Finally, we assessed whether there is a critical threshold of luminal/myoepithelial cell ratio that uncovers the bipotentiality of stem cells. Transplantation of FACS-isolated YFP+ myoepithelial cells and Tomato+ luminal cells showed that decreasing the luminal/myoepithelial cell ratio to 1/5, which is about ten times lower than physiological conditions, markedly increased the ability of myoepithelial cells to differentiate into luminal cells, as about half of the grafts were exclusively derived from YFP+ myoepithelial cells (Fig. 5d–f and Supplementary Table 1), whereas the other half was composed of a mixture of YFP+ myoepithelial cells and Tomato+ luminal cells (Fig. 5g–i and Supplementary Fig. 31).

Discussion

Our study shows that the mammary gland initially develops from multipotent embryonic K14+ progenitors, which give rise to both myoepithelial cells and luminal cells, as has been suggested previously25. During puberty and homeostasis, the expansion and maintenance of each lineage is ensured by the presence of two types of lineage-restricted stem cell, able to differentiate into either myoepithelial or luminal lineages, rather than being maintained by rare multipotent stem cells (Supplementary Fig. 32). Our data cannot rule out that some rare multipotent stem cells that were not targeted by the Cre lines used in this study exist in the mammary epithelium. However, the long-term maintenance and stable frequency of YFP+ cells, their ability to be serially transplanted as well as their massive expansion during pregnancy and lactation clearly show that unipotent stem cells are not replaced by multipotent stem cells over time and that the contribution of multipotent stem cells to mammary gland morphogenesis and adult maintenance, if it exists, is very limited under physiological conditions.

Consistent with our data, previous experiments in which labelled and non-labelled MECs have been transplanted into the fat pad showed that the new mammary glands were composed of mixture of labelled and unlabelled cells11,19,26–29, suggesting that multiple progenitors contribute to mammary gland development and adult maintenance rather than being performed by rare stem cells. In humans, analysis of X-chromosome inactivation indicates that breast epithelium is organized into multiple discrete regions sharing the same inactive X chromosome.

Figure 5 | Myoepithelial but not luminal stem cells can be forced to adopt a multipotent fate in mammary reconstitution assays. a, Whole-mount of the graft obtained after the transplantation of FACS-isolated YFP+CD29loCD24+ cells. b, c, Immunostaining of K8 (b) and K5 (c) and YFP. d–f, Transplantation of 105 FACS-isolated YFP+CD29loCD24+ cells together with 2,000 Tomato+CD29loCD24+ cells into the mammary fat pads of NOD/SCID mice. and suggested the existence of multiple stem cells scattered throughout the gland.

Our study also demonstrates that transplantation assays, although extremely informative about the differentiation potential of tissue-specific stem cells, can be misleading in extrapolating the differentiation potential of stem cells under physiological conditions. These results may explain why genetically altered strains of mice that lack basal mammary stem cells in transplantation assays show no particular defects in development or pregnancy. The very low frequency of luminal differentiation of transplanted unipotent myoepithelial stem cells when luminal cells are present within the graft at the physiological ratio, and the increase in the multipotent differentiation of myoepithelial cells when luminal cells were depleted, suggested that either luminal cells restrict the differentiation potential of myoepithelial stem cells or that the differentiation of myoepithelial stem cells into luminal cells is a relatively rare event compared to the natural differentiation of luminal stem cells, and consequently these rare multipotent clones were outcompeted by clones originating from luminal stem cells in these non-limited dilution experiments. The reason why myoepithelial cells can adopt a multipotent fate and are able to regenerate a complete mammary gland upon transplantation remains elusive. One possibility would be that mammary reconstitution assays recapitulate the process of mammary gland development and adult K14/K5 + stem cells are more prone to dedifferentiate into K14/K5 embryonic multipotent mammary progenitors under these conditions.

**METHODS SUMMARY**

YFP expression was induced in K8-CreER/Rosa-YFP, K18-CreER/Rosa-YFP and K5-CreER/Rosa-YFP female mice by intraperitoneal tamoxifen injection and in K14-rta/Tet-O-Cre-Rosa-YFP mice by oral administration of doxycycline food or by intraperitoneal injection. Immunostaining was performed as described. Mammary glands were dissected and lymph nodes removed. Tissues were cut in pieces of 1 mm 3 and digested in HBSS plus 300 U ml -1 collagenase plus 300 μg ml -1 hyaluronidase for 2 h at 37 °C under shaking. EDTA was added for 10 min, followed by trypsin-EGTA for 2 min. Cell labelling, flow cytometry and sorting were performed as described. Dead cells were excluded with DAPI, CD45 - , CD31 - and CD140a - cells were excluded (Lin + ) before analysis. Unsorted mammary cells or FACS-isolated cells were resuspended in 10 ml PBS and injected into the cleared mammary fat pad of NOD/SCID female mice. Recipient mice were mated 4 weeks after the transplantation and analysed 3 weeks later.

METHODS

**Mice.** Rosa-YFP<sup>1</sup>, Rosa-Tomato<sup>4</sup>, and Lgr5-GFP-CreER mice<sup>4</sup> were obtained from the Jackson Laboratory. K14-Cre transgenic mice<sup>5</sup> and K14-rta<sup>6</sup> mice were provided by E. Fuchs. TetO-Cre mice<sup>5</sup> were provided by A. Nagy. The generation of K18-CreER mice was as previously described<sup>5</sup>. Mice colonies were maintained in a certified animal facility in accordance with European guidelines. These experiments were approved by the local ethical committee (CEBEA).

**Generation of K8-CreER mice.** The CreERT2 fragment (supplied by P. Chambon) preceded by the β-globin intron and followed by a 5′-204A polymer signal was subcloned into pBluescript II SK<sup>®</sup>. The 3.5-kb sequence upstream of the ATG codon of the murine K8 gene, obtained from the BAC clone RP23-254K21 (BACPAC Resources Center, Children’s Hospital Oakland Research Institute), was inserted into the forward primer 5′-GGGTGACATCTGGCTCCCTCGTGT-3′ and the reverse primer 5′-GGGACAGCCGCCAGGAAGGGC-3′, was cloned upstream of the β-globin intron. The resulting K8-CreER fragment of 6.3 kb was released from the backbone by NotI digestion and was microinjected into fertilized oocytes to generate transgenic mice (Jacquemin laboratory). Seven transgenic founders were first identified by PCR, out of 27 mice born. Expression profiles of the K8-CreER founders were screened with reporter Rosa-YFP mice. Four founders expressed the YFP in cells expressing the endogenous K8, and K8 founder K8 was used throughout this study.

**Generation of K5-CreER mice.** The CreERT2 fragment, preceded by IRES, was inserted into the 3′ UTR of Krt5 in 129-derived ES cells. Correctly targeted cells were injected into B6 blastocysts. The neo selection cassette was removed by crossing a chimaeric K5-CreER male to a β-actin-floxed female (B6SJL-Tg(ActFtLP)9205Sym)). First generation of animals backcrossed to B6 were crossed with Rosa-YFP mice.

**Targeting YFP or Tomato expression.** K14-Cre/Rosa-YFP female mice express YFP in all cells derived from K14-expressing cells, whereas K14-Cre/Rosa-Tomato express Tomato in all cells derived from K14-expressing cells. For lineage tracing induced at 4 weeks or at 8 weeks, K8-CreER/Rosa-YFP, K18-CreER/Rosa-YFP, K5-CreER/Rosa-YFP, and Lgr5-GFP-CreER/Rosa-Tomato female mice were induced with 15 mg of tamoxifen (Sigma) by intraperitoneal injection. For clonal analysis by confocal microscopy, K8-CreER/Rosa-YFP, K14-CreER/Rosa-YFP, and K5-CreER/Rosa-YFP newborn mice were induced with 125 μg tamoxifen (5 μl of 25 mg ml<sup>-1</sup> solution) and K14-rta/TetO-Cre/Rosa-YFP female mice were induced with 25 μg doxycycline (Sigma) (5 μl of 5 mg ml<sup>-1</sup> solution diluted in sterile PBS) by intraperitoneal injection. For two-dimensional clonal analysis, K8-CreER/Rosa-YFP and K18-CreER/Rosa-YFP female mice were induced respectively with 1 mg and 10 mg tamoxifen and K14-rta/TetO-Cre/Rosa-YFP female mice were induced with 1 mg of doxycycline by intraperitoneal injection. For clonal analysis by confocal microscopy, K8-CreER/Rosa-YFP and K5-CreER/Rosa-YFP female mice were induced respectively with 0.2 and 7.5 mg tamoxifen by intraperitoneal injection.

**Histology and immunostaining.** Dissected mammary glands were pre-fixed for 2 h in 4% paraformaldehyde at room temperature. Tissues were washed three times with PBS for 5 min and incubated overnight in 30% sucrose in PBS at 4 °C. Tissues where then embedded in OCT and kept at −80 °C. Sections of 5 μm (for epifluorescence analysis) or 50 μm (for confocal analysis) were cut using a HM560 Microm cryostat (Micron Instruments).

Five-micrometre sections were incubated in blocking buffer (5% NDS/1% BSA/0.2% Triton in PBS) for 1 h at room temperature. The primary anti-canal antibodies combinations were incubated overnight at 4 °C. Sections were then rinsed three times for 5 min in PBS and incubated with proper secondary antibodies diluted at 1:400 in blocking buffer for 1 h at room temperature. Fifty-micrometre sections were incubated in blocking buffer (5% NDS/1% BSA/0.5% Triton/0.1% Tween 20 in PBS) for 2 h at room temperature. The primary anti-canal antibodies combinations were incubated overnight at 4 °C. Sections were then rinsed three times in PBS for 45 min and incubated with proper secondary antibodies diluted at 1:400 in blocking buffer overnight at 4 °C. The following primary antibodies were used: anti-GFP (rabbit, 1:1,000, Molecular Probes), anti-GFPC (chicken, 1:4,000, abcam), anti-K8 (rat, 1:500, Developmental Studies Hybridoma Bank), anti-K14 (rabbit, 1:2,000, Covance), anti-K14 (chicken, 1:1,000, Covance), anti-K7 (rabbit, 1:1,000, Covance), anti-K19 (rat, 1:500, Developmental Studies Hybridoma Bank), Cy3-conjugated anti-SMA (mouse, 1/1,000, Sigma), NAuLIIb (rabbit, 1/300, prepared by P. Bere).</p>
classes according to their size, and their frequency was calculated as the percentage of the total number of clones. The mean number of clones per 1,000 cells was calculated at the different time points studied and normalized as the percentage of the number of clones counted 1 week after tamoxifen administration. For the confocal analysis of size of clones in K8-CreER/Rosa-YFP mice, 69 and 197 clones were analysed respectively 1 week and at 4 weeks after tamoxifen induction.
